

Axial piston variable pump A11V(L)O series 1x

- ▶ All-purpose high pressure pump
- ▶ Size 40 to 260
- ▶ Nominal pressure 350 bar
- ▶ Maximum pressure 400 bar
- ▶ Open circuit

Features

- ▶ Through-drive for mounting of further pumps up to same size
- ▶ Optional with charge pump for sizes 130 to 260
- ▶ Higher speeds are possible for the version with charge pump (A11VLO)
- ▶ Large variety of controls
- ▶ Swashplate design
- ▶ Compact design
- ▶ High efficiency
- ▶ High power density

Hydraulic fluid

The axial piston unit is designed for operation with HLP mineral oil according to DIN 51524. Application instructions and requirements for hydraulic fluid selection, behavior during operation as well as disposal and environmental protection should be taken from the following data sheets before the start of project planning:

- ▶ 90220: Hydraulic fluids based on mineral oils and related hydrocarbons
- ▶ 90221: Environmentally acceptable hydraulic fluids
- ▶ 90223: Fire-resistant, water-containing hydraulic fluids (HFC/HFB/HFAE/HFAS)

Selection of hydraulic fluid

Bosch Rexroth evaluates hydraulic fluids on the basis of the Fluid Rating according to the technical data sheet 90235.

Hydraulic fluids with positive evaluation in the Fluid Rating are provided in the following technical data sheet:

- ▶ 90245: Bosch Rexroth Fluid Rating List for Rexroth hydraulic components (pumps and motors)

Selection of hydraulic fluid shall make sure that the operating viscosity in the operating temperature range is within the optimum range (ν_{opt} ; see selection diagram).

Viscosity and temperature of hydraulic fluids

	Viscosity	Shaft seal	Temperature ³⁾	Remarks
Cold start	$\nu_{max} \leq 1600 \text{ mm}^2/\text{s}$	NBR ²⁾	$\vartheta_{St} \geq -40 \text{ }^\circ\text{C}$	$t \leq 3 \text{ min}$, without load ($p \leq 50 \text{ bar}$), $n \leq 1000 \text{ rpm}$ Permissible temperature difference between axial piston unit and hydraulic fluid in the system maximum 25 K
		FKM	$\vartheta_{St} \geq -25 \text{ }^\circ\text{C}$	
Warm-up phase	$\nu = 1600 \dots 400 \text{ mm}^2/\text{s}$			$t \leq 15 \text{ min}$, $p \leq 0.7 \times p_{nom}$ and $n \leq 0.5 \times n_{nom}$
Continuous operation	$\nu = 400 \dots 10 \text{ mm}^2/\text{s}^{1)}$	NBR ²⁾	$\vartheta \leq +85 \text{ }^\circ\text{C}$	Measured at port T
		FKM	$\vartheta \leq +110 \text{ }^\circ\text{C}$	
	$\nu_{opt} = 36 \dots 16 \text{ mm}^2/\text{s}$			Optimal operating viscosity and efficiency range
Short-term operation	$\nu_{min} = 10 \dots 7 \text{ mm}^2/\text{s}$	NBR ²⁾	$\vartheta \leq +85 \text{ }^\circ\text{C}$	$t \leq 3 \text{ min}$, $p \leq 0.3 \times p_{nom}$, measured at port T
		FKM	$\vartheta \leq +110 \text{ }^\circ\text{C}$	

▼ Selection diagram

¹⁾ This corresponds, for example on the VG 46, to a temperature range of +4 °C to +85 °C (see selection diagram)

²⁾ Special version, please contact us

³⁾ If the temperature at extreme operating parameters cannot be adhered to, please contact us.

Filtration of the hydraulic fluid

Finer filtration improves the cleanliness level of the hydraulic fluid, which increases the service life of the axial piston unit.

A cleanliness level of at least 20/18/15 is to be maintained according to ISO 4406.

At a hydraulic fluid viscosity of less than 10 mm²/s (e.g. due to high temperatures during short-term operation) at the drain port, a cleanliness level of at least 19/17/14 according to ISO 4406 is required.

For example, a viscosity of 10 mm²/s corresponds to the following temperatures with the following media:

- ▶ HLP 32 a temperature of 73 °C
- ▶ HLP 46 corresponds to a temperature of 85 °C

Case flushing

If a variable displacement pump with control device EP, HD or with stroke limiter (H1, H2, U2, U6) is operated for a longer period of time (*t* > 10 min) with zero flow or working pressure < 15 bar, housing flushing via the connections **T₁**, **T₂** or **R** is required.

NG	40	60	75	95	130	145	190	260
<i>q_{V flush}</i> (l/min)	2	3	3	4	4	4	5	6

The need for housing flushing is eliminated at the version with charge pump (A11VLO).

Charge pump (impeller)

The charge pump is a centrifugal pump with which the A11VLO is filled and therefore can be operated at higher rotational speeds. This also simplifies cold starting at low temperatures and high viscosity of the hydraulic fluid. Externally increasing the inlet pressure is therefore unnecessary in most cases. Charging the reservoir with compressed air is permissible at 2 bar absolute.

Working pressure range

Pressure at port for working line A		Definition
Nominal pressure p_{nom}	350 bar	The nominal pressure corresponds to the maximum design pressure.
Maximum pressure p_{max}	400 bar	The maximum pressure corresponds to the maximum working pressure within a single operating period. The sum of single operating periods must not exceed the total operating period.
Single operating period	< 1 s	
Total operating period	300 h	
Minimum pressure $p_{\text{A absolute}}$ (high-pressure side)	see diagram "Minimum pressure (high-pressure side)"	Minimum pressure at the high-pressure side A which is required in order to prevent damage to the axial piston unit.
Rate of pressure change $R_{\text{A max}}$	16000 bar/s	Maximum permissible speed of pressure build-up and reduction during a pressure change across the entire pressure range.
Pressure at suction port S (inlet)		
Version without charge pump		
Minimum pressure $p_{\text{S min}}$	≥ 0.8 bar absolute	Minimum pressure at suction port S (inlet) which is required to prevent damage to the axial piston unit. The minimum pressure is dependent on the rotational speed and displacement of the axial piston unit (see diagram "Maximum permissible rotational speed" on page 9).
Maximum pressure $p_{\text{S max}}$	≤ 30 bar absolute ¹⁾	
Version with charge pump		
Minimum pressure $p_{\text{S min}}$	≥ 0.6 bar absolute	Minimum pressure at suction port S (inlet) which is required to prevent damage to the axial piston unit.
Maximum pressure $p_{\text{S max}}$	≤ 2 bar absolute	
Case pressure at port T ₁ , T ₂		
Maximum case pressure $p_{\text{T max}}$	2 bar	Measured at port T₁, T₂ Maximum 1.2 bar higher than inlet pressure at port S , but not higher than $p_{\text{T max}}$. A drain line to the reservoir is required.

Minimum pressure (high-pressure side)

Pressure definition

Total operating period = $t_1 + t_2 + \dots + t_n$

Notice

- ▶ Working pressure range applies when using hydraulic fluids based on mineral oils. Please contact us for values for other hydraulic fluids.
- ▶ The case pressure must be greater than the external pressure (ambient pressure) at the shaft seal.

¹⁾ > 5 bar, please contact us

- 1) The values apply for an absolute pressure (p_{absolute}) of 1 bar at suction port **S** and for operation with mineral operating fluid.
- 2) The values apply for an absolute pressure (p_{absolute}) of at least 0.8 bar at suction port **S** and for operation with mineral operating fluid.
- 3) The values apply at $V_g \leq V_{g \max}$ or when the inlet pressure (p_{absolute}) is increased at the suction port **S** (see diagram "Maximum permissible rotational speed" page 9)

- 4) The scope of application lies between 0 and the maximum permissible rotational speed. It applies for external stimuli (e.g. diesel engine 2 to 8 times rotary frequency, cardan shaft 2 times rotary frequency). The limit value is only valid for a single pump. The load capacity of the connection parts must be considered.
- 5) Higher rotational speed possible with special version after consultation.

▼ Maximum permissible rotational speed of the A11VO (speed limit)

(p_{absolute} = inlet pressure)

Permissible rotational speed depending on inlet pressure p_{absolute} and displacement volume $V_g / V_{g \text{ max}}$. Observe the max. rotational speed n_{max} .

Determination of the characteristics

Flow	$q_v = \frac{V_g \times n \times \eta_v}{1000}$	[l/min]
Torque	$M = \frac{V_g \times \Delta p}{20 \times \pi \times \eta_{\text{hm}}}$	[Nm]
Power	$P = \frac{2 \pi \times M \times n}{60000} = \frac{q_v \times \Delta p}{600 \times \eta_t}$	[kW]

Key

V_g	=	Displacement per revolution [cm^3]
Δp	=	Differential pressure [bar]
n	=	Rotational speed [rpm]
η_v	=	Volumetric efficiency
η_{hm}	=	Hydraulic-mechanical efficiency
η_t	=	Total efficiency ($\eta_t = \eta_v \times \eta_{\text{hm}}$)

Permissible radial and axial loading on the drive shafts

Size		NG	40	60	75	95	130	145	190	260

		$- F_{ax \max}$	N	1500	2200	2750	3500	4800	4800	6000	4150

Notice

- Theoretical values, without efficiency and tolerances; values rounded.
- Operation above the maximum values or below the minimum values may result in a loss of function, a reduced service life or in the destruction of the axial piston unit. Bosch Rexroth recommends testing the loads by means of experiment or calculation / simulation and comparison with the permissible values.
- Special requirements apply in the case of belt drives. Please contact us.

3) Note maximum input torque for shaft **S**!

Power controller

LR – Power controller, fixed setting

The power controller regulates the displacement of the pump depending on the working pressure so that a given drive power is not exceeded at constant drive speed. The precise control with a hyperbolic characteristic curve, provides an optimum utilization of available power. The working pressure acts on a rocker via a measuring spool moved together with the control. An externally adjustable spring force counteracts this, it determines the power setting. The depressurized basic position is $V_{g \max}$. If the working pressure exceeds the set spring force, the control valve will be actuated by the rocker and the pump will swivel back from the basic position $V_{g \max}$ toward $V_{g \min}$. Here, the leverage at the rocker may be shortened and the working pressure may rise in the same relation as the displacement is reduced ($p_B \times V_g = \text{constant}$; p_B = working pressure; V_g = displacement).

The hydraulic output power (characteristic curve LR) is influenced by the efficiency of the pump.

Setting range for beginning of control 50 to 350 bar

When ordering, state in plain text:

- ▶ Drive power P [kW]
- ▶ Drive speed n [rpm]
- ▶ Maximum flow $q_{V \max}$ [l/min]

Please contact us if you need a performance chart.

▼ Characteristic curve LR

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LRC – Override with cross sensing

Cross sensing is total capacity control (high-pressure-dependent) that connects two equally sized A11VO pumps with LRC controllers in power control. If one pump is operating at pressures below the set beginning of control, the unused drive power is available to the other pump, up to 100 % in borderline cases. A total drive power is thus distributed between two consumers according to demand.

Freed-up power due to pressure cut-off or other overrides is not taken into account.

Half-sided cross sensing function

When using the LRC controller on the 1st pump (A11VO) and a power-controlled pump with through-drive and without cross-sensing, which is also mounted at the drive, the required power for the 2nd pump deducted from the settings of the 1st pump. The 2nd pump has priority in the total power setting.

For design of the controller of the 1st pump, the size and the beginning of control of the power controller of the 2nd pump are required.

▼ **Circuit diagram NG 40 to 145**

▼ Circuit diagram NG 190 to 260

LR3 – High-pressure-dependent override

The high-pressure-dependent power override is a total power control where the working pressure of a mounted fixed pump is applied to the power setting (port **Z**).

Therefore, the A11VO can be set to 100 % of the total drive power. The power setting of the A11VO is reduced proportionally to the load-dependent increase in the working pressure of the fixed pump. The fixed pump has priority in the total power setting.

The measuring surface for the power reduction is adapted to the displacement of the fixed pump.

▼ **Circuit diagram NG 40 to 145**

▼ **Circuit diagram NG 190 to 260**

LG1/2 – Pilot-pressure related override

An external pilot pressure acts on the setting spring of the power controller via port **Z**.

The mechanically adjusted basic power setting can be varied by means of different pilot pressure settings.

If the pilot pressure signal is adjusted by a load limiting control, the power reduction of all consumers is reduced to match the available power from the diesel engine.

The pilot pressure for power influencing is generated by an external control element which is not part of the A11VO (e.g. BODAS LLC – Application software Load limiting control (data sheet 95312)).

LG1 Negative power override

With negative power override LG1, the force resulting from the pilot pressure counteracts the setting spring of the power controller.

Higher pilot pressure = reduced power.

Design recommendation for the control fluid requirement at $v = 10 \text{ mm}^2/\text{s}$ is 0.9 l/min for the LG1 function.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LG2 Positive power override

With positive power override LG2, the force resulting from the pilot pressure supports the setting spring of the power controller.

Higher pilot pressure = increased power.

Design recommendation for the control fluid requirement at $v = 10 \text{ mm}^2/\text{s}$ is 1.2 l/min for the LG2 function.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LE2 – Electrically proportional override (negative control)

A control current acts against the adjustment spring of the power controller via a proportional solenoid. The mechanically adjusted basic power setting can be reduced by means of different control current settings. Increasing control current = reduced power.

If the control current signal is variably controlled via a load limiting control, the power draw of all consumers is adjusted to the power draw possible for the diesel engine (e.g. BODAS LLC – Application software Load limiting control (data sheet 95312) in BODAS controller RC2-2). Direct current of 24 V (LE2) is required to control the proportional solenoid.

Technical data, solenoid	LE2
Voltage	24 V (±20 %)
Control current	
Start of control	200 mA
End of control	600 mA
Current limit	0.77 A
Nominal resistance (at 20 °C)	22.7 Ω
Dither frequency	100 Hz
Duty cycle	100 %
Type of protection: see connector version page 69	

▼ **Effect of power override with increasing pressure or current**

▼ **Circuit diagram NG 40 to 145**

▼ **Circuit diagram NG 190 to 260**

LRD – With pressure cut-off

The pressure cut-off is a pressure control which adjusts the displacement of the pump back to $V_{g \min}$ after reaching the set pressure command value.

This function overrides the power controller, i.e. the power control function is executed below the pressure command value.

The valve for pressure cut-off is integrated in the controller housing and is permanently set to a pressure command value at the factory.

Setting range from 50 to 350 bar.

▼ Characteristic curve

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LRDS – With pressure cut-off and load sensing

The load sensing controller works as a load-pressure controlled flow controller and adjusts the displacement of the pump to the volume required by the consumer.

The flow of the pump is then dependent on the cross section of the external metering orifice (1), which is located between the pump and the consumer. Below the power curve and the setting of the pressure cut-off and within the control range of the pump, the flow is independent of the load pressure.

The metering orifice is usually a separately located load sensing directional valve (control block). The position of the directional valve spool determines the opening cross-section of the metering orifice and thus the flow of the pump.

The load sensing controller compares pressure before and after the metering orifice and keeps the pressure drop (differential pressure Δp) across the orifice and therefore the flow constant.

If the differential pressure Δp at the metering orifice increases, the pump is swiveled back (towards $V_{g \min}$), if the differential pressure Δp decreases the pump is swiveled out (towards $V_{g \max}$), until equilibrium in the valve is restored.

$$\Delta p_{\text{metering orifice}} = p_{\text{pump}} - p_{\text{consumer}}$$

The setting range for Δp is between 14 bar and 25 bar. The default setting is 18 bar (please specify in plain text). The stand-by pressure in zero-stroke operation (metering orifice plugged) is slightly above the Δp setting. In a standard LS system, the pressure cut-off is integrated in the pump controller. In an LUDV system, the pressure cut-off is integrated in the LUDV valve block. The metering orifice 1 (control block) is not included in the scope of delivery.

Design recommendation for the control fluid requirement at $v = 10 \text{ mm}^2/\text{s}$ is 3.7 l/min for the LS function.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

▼ Characteristic curve

LRS2 – With load sensing, electrically overridable

By connecting a control current on a proportional solenoid, the differential pressure Δp of the load sensing control can be overridden proportionally.

Increasing current = lower Δp setting.

An example of this is shown in the characteristic curve below. Please consult us before carrying out project planning.

For technical data of solenoid, see page 14 (LE2)

▼ Characteristic curve

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LRS5 – With load sensing, hydraulically overridable

By connecting an external pilot pressure to port Z, the differential pressure Δp of the load sensing control can be overridden proportionally.

Increasing pilot pressure = lower Δp setting.

An example of this is shown in the characteristic curve below. Please consult us before carrying out project planning.

▼ Characteristic curve

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LR... – with stroke limiter

Due to the stroke limiter, it is possible to change or limit the displacement of the pump continuously across the entire control range. At the LRH, the displacement is adjusted proportionally to the pilot pressure p_{st} (max. 40 bar) applied at port **Y** or, at LRU, by the control current applied at the proportional solenoid. Direct current of 24 V (U2, U6) is required to control the proportional solenoid.

The stroke limiter is overridden by the power controller, i.e. below the power controller characteristic curve (hyperbolic characteristic curve) the displacement volume is adjusted depending on the control current or pilot pressure. If the set flow or working pressure exceeds the power control characteristic, the power control overrides and reduces the displacement along the hyperbolic characteristic.

With electric stroke limiter LRU2, LRU6 and hydraulic stroke limiter LRH2, a control pressure of 30 bar is needed to swivel the pump from its initial position $V_{g \max}$ to $V_{g \min}$. The required control power is taken from the working pressure or the external control pressure applied to port **G**.

To ensure that the stroke limiter functions at a low working pressure of < 30 bar, port **G** must be supplied with an external control pressure of about 30 bar.

Notice

- ▶ If no external control pressure is connected to **G**, the shuttle valve must be removed or relieved to the reservoir.
- ▶ The proportional solenoids in the U6 version have manual override and spring return.

LRH1 – Hydraulic stroke control (negative control)

With pilot-pressure related control, the pump displacement is adjusted proportionally and continuously with a pilot pressure applied at port **Y**.

Basic position without pilot signal is $V_{g \max}$.

- ▶ Control from $V_{g \max}$ to $V_{g \min}$
 With increasing pilot pressure the pump swivels to a smaller displacement.
- ▶ Setting range for beginning of control (at $V_{g \max}$)
 4 to 10 bar State the beginning of control in plain text in the order.
- ▶ Maximum permissible pilot pressure $p_{St \max} = 40$ bar

The required control fluid is taken from the working pressure or the external control pressure applied to port **G**.

In order for the pump to be moved from the basic position zero or at low working pressure, port **G** must be supplied with external control pressure of at least 30 bar, maximum 40 bar.

Design recommendation for the control fluid requirement at $v = 10 \text{ mm}^2/\text{s}$ is 1.2 l/min for the H1 function.

Notice

If no external control pressure is connected to **G**, this must be indicated in plain text.

In this case, the shuttle valve is not included in the scope of delivery.

Without external control pressure, the stroke control has only limited functionality. Please contact us.

▼ Characteristic curve H1

Pilot pressure increase $V_{g \max}$ to $V_{g \min}$: $\Delta p = 25$ bar

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LRH2 – Hydraulic stroke control (positive control)

With pilot-pressure related control, the pump displacement is adjusted proportionally and continuously with a pilot pressure applied at port **Y**.

Start of adjustment without pilot signal is $V_{g \min}$ (at working pressure or external control pressure >30 bar).

► Control from $V_{g \min}$ to $V_{g \max}$

With increasing pilot pressure the pump swivels to a higher displacement.

► Setting range for beginning of control (at $V_{g \min}$)

4 to 10 bar State the beginning of control in plain text in the order.

► Maximum permissible pilot pressure $p_{St \max} = 40$ bar

The required control fluid is taken from the working pressure or the external control pressure applied to port **G**. In order for the pump to be moved from the basic position zero or at low working pressure, port **G** must be supplied with external control pressure of at least 30 bar, maximum 40 bar.

Design recommendation for the control fluid requirement at $\nu = 10 \text{ mm}^2/\text{s}$ is 0.3 l/min for the H2 function.

Notice

- If no external control pressure is connected to **G**, this must be indicated in plain text.
In this case, the shuttle valve is not included in the scope of delivery.
- Without external control pressure, the stroke control has only limited functionality. Please contact us.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

LRU2/LRU6 – Electric stroke control (positive control)

With the electrical stroke control with proportional solenoid, the pump displacement is steplessly adjusted in proportion to the current via the magnetic force.

Beginning of control without pilot signal is $V_{g \min}$ (at working or external control pressure > 30 bar).

The mechanically depressurized basic position is $V_{g \max}$.

With increasing control current the pump swivels to a greater displacement (from $V_{g \min}$ to $V_{g \max}$).

The required control fluid is taken from the working pressure or the external control pressure applied to port **G**. In order for the pump to be moved from the basic position zero or at low working pressure, port **G** must be supplied with external control pressure of at least 30 bar, maximum 40 bar.

Notice

- ▶ If no external control pressure is connected to **G**, this must be indicated in plain text.
In this case, the shuttle valve is not included in the scope of delivery.
- ▶ Without external control pressure, the stroke control has only limited functionality. Please contact us.

Pressure controller

DR – Pressure controller

The pressure controller limits the maximum pressure at the pump outlet within the control range of the variable pump. The variable pump only supplies as much hydraulic fluid as is required by the consumers.

If the working pressure exceeds the pressure command value at the pressure valve, the pump will regulate to a smaller displacement to reduce the control differential.

- ▶ Basic position in depressurized state: $V_{g \max}$
- ▶ Setting range for pressure control: 50 to 350 bar.
Specify pressure controller setting in plain text when ordering.

▼ Characteristic curve

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

DRS – Pressure controller with load sensing

The load sensing controller works as a load-pressure controlled flow controller and adjusts the displacement of the pump to the volume required by the consumer. The flow of the pump is then dependent on the cross section of the external metering orifice **(1)**, which is located between the pump and the consumer. Below the setting of the pressure controller and within the control range of the pump, the flow is not dependent on the load pressure.

The metering orifice is usually a separately located load sensing directional valve (control block).

The position of the directional valve spool determines the opening cross-section of the metering orifice and thus the flow of the pump.

The load sensing controller compares the pressure upstream the metering orifice to the one downstream the orifice and keeps the pressure drop (differential pressure Δp) occurring here and thus the flow constant.

If the differential pressure Δp at the metering orifice rises, the pump is swiveled back (toward $V_{g \min}$). If the differential pressure Δp drops, the pump is swiveled out (toward $V_{g \max}$) until equilibrium at the metering orifice is restored.

$$\Delta p_{\text{metering orifice}} = p_{\text{pump}} - p_{\text{consumer}}$$

- ▶ Setting range for Δp 14 to 25 bar (please state in plain text)
- ▶ Standard setting 18 bar

The stand-by pressure in zero-stroke operation (metering orifice closed) is slightly higher than the Δp setting.

The metering orifice **1** (control block) is not included in the scope of delivery.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

▼ Characteristic curve

DRG – Pressure controller, hydraulically remote-controlled

On the remote-controlled pressure controller, the setting of the pressure controller can be overridden by a separate pressure relief valve (1) to set a lower pressure command value.

Setting range from 50 to 350 bar.

In addition a separately configured 2/2 directional valve (2) can be operated to start the pump with low working pressure (standby pressure).

Setting range for Δp 14 to 25 bar, standard setting 22 bar (when ordering, please state in plain text)

Both functions can be used individually or in combination (see circuit diagram).

The external valves are not included in the scope of delivery.

As a separate pressure relief valve (1) we recommend: DBDH 6 (manual actuation) see data sheet 25402.

▼ Characteristic curve

Notice

Remote-controlled pressure cut-off is also possible in connection with LR, HD and EP.

▼ Circuit diagram NG 40 to 145

▼ Circuit diagram NG 190 to 260

DRL – Pressure controller for parallel operation

The DRL pressure controller is suitable for pressure control of several A11VO axial piston pumps in parallel operation pumping into a common pressure line. The pressure cut-off has a pressure increase of approx. 15 bar from $q_{v \max}$ to $q_{v \min}$. The pump regulates therefore to a pressure dependent swivel angle. This results in a stable controller behavior. With the externally installed pressure relief valve **(1)** the nominal pressure command value of all pumps connected to the system is adjusted to the same value. Setting range from 50 to 350 bar. Each pump can be individually unloaded from the system by a separately installed 3/2 directional valve **(2)**. The check valves **(3)** in the working line (port **A**) or control line (connection **X**) must be generally provided. The external valves are not included in the scope of delivery. As a separate pressure relief valve **(1)** we recommend: DBDH 6 (manual actuation) see data sheet 25402.

By using combination pumps, it is possible to have independent circuits without the need for splitter gearboxes. When ordering combination pumps the type designations for the 1st and the 2nd pump must be joined by a "+".

Order example:

A11VO130LRDS/10R-NZD12K61+ A11VO60LRDS/10-NZC12N00

A tandem pump, with two pumps of equal size, is permissible without additional supports, assuming that the dynamic mass acceleration does not exceed maximum 10 g (= 98.1 m/s²).

For combination pumps consisting of more than two pumps, the mounting flange must be calculated for the permissible mass torque.

▼ Total length of a combination pump

Notice

- The combination pump type code is shown in shortened form in the order confirmation.
- The permissible through-drive torques are to be observed (see page 10).

¹⁾ When using the Z-shaft (splined shaft DIN 5480) for the mounted pump (2nd pump)

Swivel angle indicator

Optical swivel angle indicator V

With the optical swivel angle indicator, the swivel position of the pump is indicated by a mechanical indicator on the side of the housing.

▼ Circuit diagram

▼ Swivel angle indicator

NG	A	C

60	not available	
75	60.7	97.0
95	63.5	104.0
130	70.9	112.0
190	87.6	123.5
260	87.6	137.0

Electric swivel angle sensor R

With electric swivel angle indicator, the pump swivel position is measured by an electric swivel angle sensor. It has a robust, sealed housing and an integrated electronics unit that has been developed for automotive applications.

As an output the Hall effect swivel angle sensor delivers a voltage signal proportional to the swivel angle.

▼ **Circuit diagram**

Characteristics		
Supply voltage U_b	10 ... 30 V DC

Connector for solenoids

DEUTSCH DT04-2P-EP04

Molded, 2-pin, without bidirectional suppressor diode

The following type of protection ensues with the installed mating connector:

- ▶ IP67 (DIN/EN 60529) and
- ▶ IP69K (DIN 40050-9)

▼ Switching symbol

Mating connector DEUTSCH DT06-2S-EP04

Consisting of	DT designation
1 housing	DT06-2S-EP04
1 wedge	W2S
2 sockets	0462-201-16141

The mating connector is not included in the scope of delivery.

This can be supplied by Bosch Rexroth on request (material number R902601804).

Notice

- ▶ If necessary, you can change the position of the connector by turning the solenoid body.
- ▶ The procedure is defined in the instruction manual.

Installation instructions

General

The axial piston unit must be filled with hydraulic fluid and vented during commissioning and operation. This must also be observed during longer standstills, as the axial piston unit can empty itself via the hydraulic lines. Particularly in the installation position "drive shaft upwards", filling and air bleeding must be carried out completely as there is, for example, a danger of dry running. The leakage in the housing area must be directed to the reservoir via the highest drain port (**T₁/T₂**). For combination pumps, the leakage must be drained off at each single pump.

If a shared drain line is used for several units, make sure that the respective case pressure in each unit is not exceeded. The shared drain line must be dimensioned to ensure that the maximum permissible case pressure of all connected units is not exceeded in any operating condition, particularly at cold start. If this is not possible, separate drain line must be laid, if necessary.

To prevent the transmission of structure-borne noise, use elastic elements to decouple all connecting lines from all vibration-capable components (e.g. reservoir, frame parts).

Under all operating conditions, the suction line and drain line must flow into the reservoir below the minimum fluid level of the reservoir. The permissible suction height h_S results from the total pressure loss, but must not be higher than $h_{S\ max} = 800\text{ mm}$. The minimum suction pressure at port **S** of 0.8 bar absolute (without charge pump) or 0.6 bar absolute (with charge pump) must not be fallen below during operation (cold start 0.5 bar absolute). For the reservoir design, ensure that there is an adequate distance between the suction line and the drain line. We recommend using a baffle (baffle plate) between suction line and drain line. A baffle improves the air separation ability as it gives the hydraulic fluid more time for desorption. Apart from that, this prevents the heated return flow from being drawn directly back into the suction line. The suction port must be supplied with air-free, calmed and cooled hydraulic fluid.

Installation position

See the following examples **1** to **10**. Further installation positions are available upon request. Recommended installation position: **1** and **2**

Key	
F₁/F₂	Filling / Air bleeding
S	Suction port
T₁/T₂	Drain port
SB	Baffle (baffle plate)
h_{t min}	Minimum required immersion depth (200 mm)
h_{min}	Minimum required distance to reservoir bottom (100 mm)
h_{ES min}	Minimum height required to prevent axial piston unit from draining (25 mm)
h_{S max}	Maximum permissible suction height (800 mm)

Notice

- ▶ In certain installation positions, an influence on the control or control can be expected. Gravity, dead weight and case pressure can cause minor characteristic shifts and changes in actuating time.
- ▶ Ports **F₁** and **F₂** are part of the external piping and must be provided on the customer side to make filling and air bleeding easier.

Below-reservoir installation (standard)

Below-reservoir installation means that the axial piston unit is installed outside of the reservoir below the minimum fluid level.

▼ Installation position 1

▼ Installation position 2

▼ Installation position 3

▼ Installation position 4

For key, see page 70.

Above-reservoir installation

Above-reservoir installation means that the axial piston unit is installed above the minimum fluid level of the reservoir. To prevent the axial piston unit from draining, a height difference $h_{ES\ min}$ of at least 25 mm at port **R** is required in position 7.

The version A11VLO (with charge pump) is not intended for above-reservoir installation.

Recommendation for installation position **7** (shaft upward): A check valve in the drain line (cracking pressure 0.5 bar) can prevent draining of the housing area. For control options with pressure controllers, stroke limiters, HD and EP control, the minimum displacement setting must be $V_g \geq 5\ \% \ V_{g\ max}$.

Observe the maximum permissible suction height $h_{S\ max} = 800\ mm$.

Installation position 5

Installation position 6

Installation position 7

For key, see page 70.

Inside-reservoir installation

Inside-reservoir installation is when the axial piston unit is installed in the reservoir below the minimum fluid level. The axial piston unit is completely below the hydraulic fluid. If the minimum fluid level is equal to or below the upper edge of the pump, see chapter "Above-reservoir installation". Axial piston units with electric components (e.g. electric controls, sensors) may not be installed in a reservoir below the fluid level. If inside-reservoir installation is intended nevertheless, the IP protection class and the medium compatibility of the electric components used must be checked in the individual case. Please consult your proper contact person at Bosch Rexroth to commission an examination of the medium compatibility.

▼ Installation position 8

Air bleeding the housing	Filling
T₁	The housing of the axial piston unit is to be filled via T₁ before attachment of the piping

▼ Installation position 9

Air bleeding the housing	Filling
R	The housing of the axial piston unit is to be filled via T₁/T₂ before attachment of the piping

▼ Installation position 10

Air bleeding the housing	Filling
R	The housing of the axial piston unit is to be filled using T₂ before attachment of the piping

Notice

- Installation of the pump with EP control in the oil reservoir only when using mineral hydraulic oils and an oil temperature in the reservoir of max. 80 °C.
- In this case, the other drain port must be plugged. The housing of the axial piston unit must be filled before fitting the piping and filling the reservoir with hydraulic fluid.

Project planning notes

- ▶ The pump is designed to be used in open circuits.
- ▶ Project planning, installation and commissioning of the axial piston units requires the involvement of skilled personnel.
- ▶ Before using the axial piston unit, please read the corresponding instruction manual completely and thoroughly. If necessary, this can be requested from Bosch Rexroth.
- ▶ Before finalizing your design, please request a binding installation drawing.
- ▶ The specified data and notes contained herein must be observed.
- ▶ Depending on the operating conditions of the axial piston unit (working pressure, fluid temperature), the characteristic curve may shift.
- ▶ Preservation: Our axial piston units are supplied as standard with preservation protection for a maximum of 12 months. If longer preservation protection is required (maximum 24 months), please specify this in plain text when placing your order. The preservation periods apply under optimal storage conditions, details of which can be found in the data sheet 90312 or the instruction manual.
- ▶ Not all versions of the product are approved for use in a safety function according to ISO 13849. Please consult the responsible contact person at Bosch Rexroth if you require reliability parameters (e.g. MTTF_D) for functional safety.

Depending on the type of control used, electromagnetic effects can be produced when using solenoids. Applying a direct voltage signal (DC) to solenoids does not create electromagnetic interference (EMI) nor is the solenoid affected by EMI. Electromagnetic interference (EMI) potential exists when operating and controlling a solenoid with a modulated direct voltage signal (e.g. PWM signal) Appropriate testing and measures should be taken by the machine manufacturer to ensure other components or operators (e.g. with pacemaker) are not affected by this potential.
- ▶ Pressure controllers are not safeguards against pressure overload. Be sure to add a pressure relief valve to the hydraulic system.
- ▶ For controllers requiring external pilot pressure, sufficient control fluid must be provided to the associated ports to ensure the required pilot pressures for the respective controller function. These controllers are subject to leakage due to their design. An increase in control fluid demand has to be anticipated over the total operating time. The design of the control fluid supply must thus be sufficiently large. If the control fluid is too low, the respective controller function may be impaired and undesired system behavior may result.
- ▶ Please note that a hydraulic system is an oscillating system. This can lead, for example, to the stimulation the natural frequency within the hydraulic system during operation at constant rotational speed over a long period of time. The excitation frequency of the pump is 9 times the rotational speed frequency. This can be prevented, for example, with suitably designed hydraulic lines.
- ▶ Please note the details regarding the tightening torques of port threads and other threaded joints in the instruction manual.
- ▶ The ports and fastening threads are designed for the $p_{\max}$ permissible pressures of the respective ports, see the connection tables. The machine or system manufacturer must ensure that the connecting elements and lines correspond to the specified application conditions (pressure, flow, hydraulic fluid, temperature) with the necessary safety factors.
- ▶ The working ports and function ports are only intended to accommodate hydraulic lines.

Safety instructions

- ▶ During and shortly after operation, there is a risk of burning on the axial piston unit and especially on the solenoids. Take the appropriate safety measures (e.g. by wearing protective clothing).
- ▶ Moving parts in control equipment (e.g. valve spools) can, under certain circumstances, get stuck in position as a result of contamination (e.g. contaminated hydraulic fluid, abrasion, or residual dirt from components). As a result, the hydraulic fluid flow and the build-up of torque in the axial piston unit can no longer respond correctly to the operator's specifications. Even the use of various filter elements (external or internal flow filtration) will not rule out a fault but merely reduce the risk.

The machine/system manufacturer must test whether remedial measures are needed on the machine for the application concerned in order to bring the driven consumer into a safe position (e.g. safe stop) and ensure any measures are properly implemented.
